

Gemini Prompt: I would like to build an app that works like a private banker, how would that work and are there any website that could be useful for doing such things or is there already one out there?

Building an app that replicates the experience of a private banker involves moving far beyond standard robo-advisory tools (like Wealthfront or Betterment). A true digital private banker needs to mirror **hyper-personalization, multi-custody tracking, custom risk profiling, and complex portfolio intelligence.**

1. How a "Digital Private Banker" App Works

To deliver the high-touch, tailored feel of elite wealth management, the app's architecture generally requires a coordinated system of four distinct layers:

The Key Technical Mechanics:

- **The Normalized Data Layer:** Unlike a standard retail app linked to one banking account, a private banking client usually has assets spread across multiple institutions, asset classes (equities, bonds, private equity, or digital assets), and currencies. The app must ingest these fragmented feeds and normalize them into a single mathematical "source of truth."

- **Portfolio Intelligence & Explainable Logic:** General-purpose AI is prone to hallucinations, which is a fatal flaw in wealth management. Instead of letting an AI calculate portfolio metrics directly, the system uses deterministic financial models (like calculating a portfolio's Beta, Sharpe ratio, or Value at Risk) and feeds those *exact mathematical outputs* to the AI. This ensures the AI explains the data accurately without inventing financial figures.
- **Contextual Agentic AI:** The AI maps real-time macroeconomic news or specific market developments directly against the client's asset allocation. If a specific index or commodity drops, the AI agent proactively determines which underlying exposures in the user's portfolio are affected and surfaces tailored rebalancing ideas.

2. Who is Already Doing This?

The financial technology space has shifted heavily into "Agentic WealthTech." Major institutions and B2B platforms are currently pioneering this exact architecture:

Incumbent Innovations

- **OCBC WoW (Whole-of-Wealth):** Launched as an AI-native banking app for high-net-worth premier clients. It utilizes interactive AI avatars (named Wendy and Wayne) that communicate via voice or text. They analyze live portfolios against the bank's research, flag risk concentrations, and deliver real-time, personalized investment ideas based on the client's specific risk profile.
- **Morgan Stanley & JPMorgan:** These firms are investing heavily in linking traditional wealth accounts with alternative assets and using internal generative AI platforms to instantly draft hyper-personalized investment proposals and automate intensive onboarding tasks like "Source of Wealth" verification.

Enterprise Infrastructure Platforms (B2B)

If you are looking for backend infrastructure or inspiration on how these apps are assembled, several specialized platforms provide the core logic:

- **Flanks (flanks.io):** A premier wealth data infrastructure tool. It connects to hundreds of global financial institutions to aggregate and reconcile multi-custody data, acting as the precise data layer that feeds financial AIs.
- **Unique AI (unique.ai):** They design agentic workflows specifically for private banking (deployed by institutions like BNP Paribas). Their platform transcribes client meetings, extracts actionable notes directly into financial CRMs, and generates compliant, highly customized investment proposals in minutes.
- **Privé Technologies (privetechnologies.com):** A modular, AI-driven wealth management platform that covers everything from digital onboarding and algorithmic risk profiling to portfolio construction and automated order execution.

3. Useful Frameworks & Tooling for Building One

If you want to build a prototype or an actual application in this space, you don't have to build the financial logic from scratch. You can stack specialized developer tools:

- **For Data Aggregation:** Use **Flanks** or **Plaid** (specifically their investments API) to securely connect to external brokerage and bank accounts.
- **For Financial Computation:** Use open-source quantitative libraries like **QuantLib** or **PyPortfolioOpt** (for mean-variance optimization and risk calculations) wrapped in a Python backend. Never let the LLM do raw portfolio math.
- **For the AI Agent Layer:** Use orchestration frameworks like **LangChain** or **LlamaIndex** configured with strict retrieval-augmented generation (RAG). You would point the LLM to process structural portfolio metrics on one end, and curated financial news feeds (via APIs like Bloomberg, Reuters, or Benzinga) on the other.
